22. ALCOHOLS, PHENOLS AND **ETHERS**

ALCOHOLS

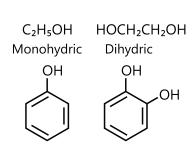

1. INTRODUCTION

- (a) These are the organic compounds in which -OH group is directly attached with carbon.
- (b) These are hydroxyl derivatives of alkanes, mono alkyl derivatives of water.
- (c) Their general formula is $C_n H_{n+1}OH$ or $C_n H_{2n+2}O$.

1.1 Classification of Alcohols

Mono, Di, Tri or Polyhydric Compounds

Alcohols and phenols may be classified as mono-, di-, tri- or polyhydric compounds depending on whether they contain one, two, three or many hydroxyl groups respectively in their structures as given below:

Monohydric Dihydric

1.1.1 Compounds Containing Csp³ – OH Bond

In this class of alcohols, the -OH group is attached to an sp³ hybridised carbon atom of an alkyl group. They are further classified

(a) Primary, secondary and tertiary alcohols: In these types of alcohols, the -OH group is attached primary secondary and tertiary carbon atom, respectively as depicted below.

Primary (1°) Secondary (2°) Tertiary (3°)

(b) Allylic alcohols: In these alcohols, the -OH group is attached to an sp³ hybridised carbon next to the carbon-carbon double bond, i.e. to an allylic carbon. For example

Tertiary (3°)

(c) Benzylic alcohols: In these alcohols, the –OH group is attached to an sp³ –hybridized carbon atom next to an aromatic ring.

For example Allylic and benzylic alcohols may be primary, secondary or tertiary

1.1.2 Compounds Containing Csp²-OH Bond

These alcohols contain –OH group bonded to a carbon- carbon double i.e., to a vinylic carbon or to an aryl carbon. These alcohols are also known as vinylic alcohols

Vinylic alcohol: CH2=CH-OH

2. PREPARATION OF ALCOHOLS

2.1 From Alkenes

$$C=C+H_2O$$
 H
 $C-C$
 H
 OH

2.1.1 By Acid Catalyzed Hydration

Alkenes react with water in the presence of acid as catalyst to form alcohol. In case of unsymmetrical alkenes, the addition reaction takes place in accordance with Markonikov's rule.

Mechanism: The mechanism of the reaction involves the following three steps:

Step 1
$$H_2O + H^+ \rightarrow H_3O^+$$

$$-\overset{}{C} = \overset{}{C} - + \overset{}{H} \xrightarrow{\overset{}{O}^+} - \overset{}{H} \xrightarrow{\overset{}{\longrightarrow} -\overset{}{C} - \overset{}{C} - + \overset{}{H}_2 \overset{}{\circ} \overset{}{\circ}}$$
Step 2 $H \xrightarrow{\overset{}{\longrightarrow} -\overset{}{C} - \overset{}{C} - \overset{}{\leftarrow} + \overset{}{H}_2 \overset{}{\circ} \overset{}{\circ} \overset{}{\longrightarrow} -\overset{}{C} - \overset{}{C} - \overset{}{C} - \overset{}{\leftarrow} + \overset{}{H}_3 \overset{}{\circ} \overset{}{\longrightarrow} \overset{\longrightarrow$

2.1.2 By Hydroboration-Oxidation

Diborane $(BH_3)_2$ reacts with alkenes to give trialkyl boranes as addition product. This is oxidized to alcohols in the presence of aq. sodium hydroxide (NaOH) and peroxide.

Note: This is the addition of water at double bond according to Anti-Markonikov Rule.

$$H_{3}C-CH=CH_{2}+ (H-BH_{2})_{3} \longrightarrow CH_{3}-CH-CH_{2}$$
 $H_{3}-CH=CH_{2}$
 $H_{3}-CH=CH_{2}$
 $H_{3}-CH=CH_{2}$
 $H_{3}-CH=CH_{2}$
 $H_{3}-CH=CH_{2}$
 $H_{3}-CH_{2}-CH_{2}$
 $H_{3}-CH_{2}-CH_{2}$

Mechanism of hydroboration - deboration

$$CH_{3}-CH=CH_{2} \xrightarrow{B_{2}H_{6}-THF/H_{2}O_{2}/OH^{-}} CH_{3}-CH_{2}-CH_{2}-OH$$

$$+CH_{3}-CH=CH_{2} \xrightarrow{CH-CH-CH_{2}} CH_{3}-CH_{2}-CH_{2}$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-CH_{2}-OH$$

$$OH_{3}-CH_{2}-OH$$

These steps are repeated thrice to form (CH₃— CH₂— CH₂)₃B and then

$$R - \stackrel{R}{\xrightarrow{H}} \xrightarrow{H - \stackrel{\circ}{\circ} - \stackrel{\circ}{\circ} - H} R - \stackrel{R}{\xrightarrow{H}} - O - O - H \xrightarrow{-H^{+}} R - \stackrel{R}{\xrightarrow{H}} - \stackrel{\circ}{\circ} - \stackrel{\circ}{\circ} - \stackrel{H}{\xrightarrow{H}} - O - O - H \xrightarrow{-H^{+}} R - \stackrel{R}{\xrightarrow{H}} - \stackrel{\circ}{\circ} - \stackrel{\circ}{\circ$$

With H_2O_2 , finally RO-B-OR is formed by above mentioned method.

OR
$$RO - B - OR \xrightarrow{3NaOH} Na_3BO_3 + 3ROH$$

2.1.3 Oxymercuration Demercuriation

Involves an electrophilic attack on the double bond by the positively charged mercury species. The product is a mercurinium ion, an organometallic cation containing a three-membered ring.

With mercuric acetate, the product is 3-methyl-2-butanol (Markonikov's addition with no rearrangement, oxymercuration-demercuration reaction)

$$\begin{array}{c}
\text{OAc} \\
\downarrow \\
\text{Hg}^{+}
\end{array}$$

$$\begin{array}{c}
\text{C-C} \\
\text{Hg}(\text{OAc}) \longrightarrow \\
\text{Mercurinium ion}
\end{array}$$

Mercuration commonly takes place in a solution containing water and an organic solvent to dissolve the alkene. Attack on the mercurinium ion by water gives (after deprotonation) an organomercurial alcohol.

Hg(OAc)
Hg(OAc)
Hg(OAc)
Hg(OAc)
Hg(OAc)
H-
$$^+$$
O:
H- $^+$ O:
H- $^+$ O:
Hg(OAc)
Hg

The second step is demercuration, to form the alcohol. Sodium borohydride (NaBH₄, a reducing agent replaces the mercuric acetate with hydrogen.)

2.2 From Carbonyl Compounds

2.2.1 By Reduction of Carbonyl Compounds

R-CHO + 2H
$$\xrightarrow{\text{LiAlH}_4 / \text{Na} + \text{C}_2\text{H}_5\text{OH}}$$
 R-CH-H $\stackrel{|}{\text{I}}$ OH $\stackrel{|}{\text{OH}}$ 1° alcohol

R-C-R + 2H $\xrightarrow{\text{LiAlH}_4 / \text{Na} + \text{C}_2\text{H}_5\text{OH}}$ R-CH-R $\stackrel{|}{\text{I}}$ OH $\stackrel{|}{\text{OH}}$ 2° alcohol

2.3 From Acid Derivatives

2.3.1 By Reduction of Acid and its Derivatives

R - C - OH + 4H
$$\xrightarrow{\text{LiAlH}_4}$$
 R-CH₂-OH

O

R - C - X + 4H $\xrightarrow{\text{LiAlH}_4}$ R-CH₂-OH + HX

O

R - C - OR' + 4H $\xrightarrow{\text{LiAlH}_4}$ R-CH₂-OH + R'OH

O

RCOOCOR + 8H $\xrightarrow{\text{LiAlH}_4}$ 2 RCH₂OH + H₂O

2.4 From Grignard Reagents

2.4.1 Reaction with Oxirane

2.4.2 Reaction with Carbonyl Compounds

$$R: Mg - X + C = O \xrightarrow{i) \text{ ether}} R - C - O - H + MgX_2$$

$$R - \overset{\mid}{C} - \overset{\mid}{O} \overset{\mid}{O} - H + \overset{\mid}{O} - H + \overset{\mid}{O} - H + \overset{\mid}{O} - H + MgX_2$$

2.4.3 Reaction with Acetaldehyde

$$CH_3$$
 CH_3 CH_3

2.4.4 Reaction with Ketone

$$CH_{3}-CH_{2}-CH_{2}-MgBr+CH_{3}$$

$$CH_{3}-CH_{2}-CH_{2}-MgBr+CH_{3}$$

$$OH_{3}-CH_{2}-CH_{2}-MgBr+CH_{3}$$

$$OH_{3}-CH_{2}-CH_{2}-MgBr+CH_{3}$$

$$OH_{3}-CH_{3}-CH_{2}-CH_{2}-MgBr+CH_{3}$$

$$OH_{3}-CH_{2}-CH_{2}-MgBr+CH_{3}$$

2-methylpentan-2-ol

2.5 By Fermentation

Fermentation is a low decomposition of complex organic compounds into simpler compound in the presence of suitable micro-organisms which are the source of biochemical catalyst known as yeast.

$${(\mathsf{C_6H_{10}O_5})_{\mathsf{n}}} \underset{\mathsf{n-Butylalcohol}}{\longleftrightarrow} \mathsf{CH_3CH_2CH_2CH_2OH} + \mathsf{CH_3COCH_3}$$

3. PHYSICAL PROPERTIES OF ALCOHOLS

- (a) The lower alcohols are liquids while higher having more than 12 carbon atoms are solids. They are colourless, neutral substance with characteristic sweet, alcoholic odour and burning taste.
- **(b)** The lower alcohols are readily soluble in water and the solubility decreases with the increase in molecular weight.

The solubility of alcohols in water can be explained due to the formation of hydrogen bond between the highly polarized –OH groups present both in alcohols and water.

However, in higher alcohols, the hydrocarbon character (alkyl chain) increases, showing a steric hindrance. Hence, the solubility in water decreases.

When the ratio of C:OH is more than 4, alcohols have little solubility in water.

(c) Boiling points of alcohols are much higher than those of the corresponding alkanes. It is due to the intermolecular hydrogen bonding present between the hydroxyl groups of the two molecules of an alcohol with the result several molecules are associated to form a large molecule.

Among the isomeric alcohols, b.p. and m.p. show the following trend.

Primary > Secondary > Tertiary

This is because of the fact that in secondary and tertiary alcohols, the alkyl part (hydrogen character) outweighs the –OH group due to branching.

(d) Lower alcohols form solid addition compounds with anhydrous metallic salts like CaCl₂ and MgCl₂, viz., CaCl₂, 4C₂H₅OH and MgCl₂.6C₂H₅OH

By analogy to water of crystallization, these alcohols molecules are referred to as alcohols of crystallization. For this reason, alcohols cannot be dried over anhydrous calcium chloride.

MASTERJEE CONCEPTS

Preparation of alcohols:

- Key takeaway Hydration and oxymercuration-demercuration gives Markonikov's product but hydroboration-oxidation gives Anti-markonikov's product.
- Misconception Hydroboration follows Markonikov's rule but in this case, the electron deficient species is Boron and not Hydrogen.
- Note On replacing water with carboxylic acid in hydroboration-oxidation, the product obtained is alkane instead of alcohol.
- Note Tertiary alcohols cannot be obtained by reduction of carbonyl compounds.
- Fact If we use NaOH as a reductant in reduction of carbonyl compounds to alcohols, the process is known as Darzen's process.
- Tips and tricks In conversion of oxirane to alcohols using Grignard's reagent, the alkyl part adds to the carbon with less steric hindrance as it proceeds via $S_{N}2$ mechanism.

Physical properties of alcohols:

Alcohols generally have high boiling point because of hydrogen bonding.

Vaibhav Krishnan (JEE 2009, AIR 22)

Illustration 1: Write the IUPAC names, as their names by Carbinol system, and classify them as 1°, 2°, 3°, allylic, vinylic, benzylic, and propargylic of the following compound. (**JEE MAIN**)

$$(A) \quad Me \qquad \qquad (B) \quad Me \\ OH \qquad \qquad (B) \quad Ph \qquad Me$$

(C)

4. CHEMICAL PROPERTIES OF ALCOHOLS

4.1 Reaction with Active Metals-Acidic Character

Alcohols are weakly acidic in nature due to which when they react with group one alkali metals they liberate hydrogen gas and form alkoxides.

$$2R - O - H + 2Na \rightarrow 2R - O^-Na^+ + H_2^{\uparrow}$$

The acidic order of alcohols is $MeOH > 1^{\circ} > 2^{\circ} > 3^{\circ}$. This acidic nature of alcohol is due to the presence of polar O-H bond.

4.2 Esterification/Reaction with Carboxylic Acid

Reaction of alcohol with carboxylic acid in presence of sulphuric acid gives an ester. In this reaction sulphuric acid react as protonating agent as well as dehydrating agent.

$$\begin{array}{c} R-O-H+H-C-R \xrightarrow{\quad conc.H_2SO_4 \quad } R-C-O-R+H_2O \\ O & O \end{array}$$

Mechanism:

$$H_2SO_4 \longrightarrow H^+ + HSO_4^-$$

Note : The above reduction is laboratory method of ester preparation.

4.3 Reaction with Acid Derivatives

When alcohols are treated with acid derivatives, hydrogen of hydroxyl group is substituted by acyl group.

$$R-O-H+R-C-O-C-R \xrightarrow{conc.H_2SO_4} R-O-C-R$$

$$\parallel \qquad \parallel \qquad \parallel \qquad \qquad \parallel$$

$$0 \qquad 0 \qquad \qquad 0$$

4.4 Reaction with Isocyanic Acid

4.5 Reaction with Ethylene Oxide

$$R-O^{\delta^{-}}H^{\delta^{+}} \xrightarrow{CH_{2}-CH_{2}} CH_{2} \xrightarrow{ROH} CH_{2}-CH_{2}$$

$$OR OH OR OR$$

$$1,2-dialkoxy ethane$$

4.6 Reaction with Diazomethane

$$R-O-H+CH_2N_2 \longrightarrow R-O-CH_3$$
 (ether)

4.7 Reaction with H₂SO₄

$$CH_3 - CH_2 - OH + H_2SO_4$$
 (excess) $140^{\circ}C \rightarrow CH_3 - CH_2 - O - CH_2 - CH_3$

Mechanism:

$$H_{2}SO_{4} \longrightarrow H^{+} + HSO_{4}^{-}$$

$$CH_{3}-CH_{2} \overset{\circ}{\circlearrowleft} + H^{+} \longrightarrow CH_{3}-CH_{2}-\overset{\circ}{\circlearrowleft} - H$$

$$H$$

$$H$$

$$-H_{2}O$$

$$CH_{3}-CH_{2}-\overset{\circ}{\circlearrowleft} - CH_{2}-CH_{3} \overset{CH_{3}-CH_{2}-OH}{\longleftarrow} CH_{3}-\overset{C}{\hookrightarrow} - CH_{2}$$

$$(protonated ether)$$

$$\downarrow -H^{+}$$

$$CH_{3}-CH_{2}-\overset{\circ}{\circlearrowleft} - CH_{2}-CH_{3}$$

(ii)
$$CH_3 - CH_2 - OH + H_2SO_4 \xrightarrow{160^{\circ}C} CH_2 = CH_2$$

(excess)

Mechanism:

$$H_2SO_4 \longrightarrow H^+ + HSO_4^-$$

$$CH_3 - CH_2 - OH + H^{+} \longrightarrow CH_3 - CH_2 - \overset{\bullet}{O} - H \xrightarrow{-H_2O} CH_3 - \overset{\bullet}{CH_2} \xrightarrow{H^{+}} CH_2 = CH_2$$

4.8 Action of Halogen Acids

Alcohol react with HX to give RX. Reactivity order of ROH is 1°>2°>3°. Hence primary alcohols react in presence of catalyst (If X is CI Luca's reagent and if X is Br small amount of H₂SO₄), but secondary and tertiary alcohols can react in absence of catalyst. However, when alcohol react with HI/Red P they reduced in hydrocarbon.

$$C_2H_5OH + HCI \xrightarrow{anhy. ZnCl_2} C_2H_5CI + H_2O$$

The reactivity of halogens is in the order: HI > HBr > HCl

S_N1 reaction with the Lucas reagent (fast)

S_N2 reaction with Lucas reagent is slow:

$$: \stackrel{CH_3CH_2CH_2}{::} \stackrel{CH_2CH_2CH_3}{::} \stackrel{CI}{:} \stackrel{CH_2CH_2CH_3}{::} \stackrel{CI}{:} \stackrel{C}{:} \stackrel{C}$$

4.9 Action of Thionyl Chloride

Alcohols react with thionyl chloride to form alkyl halide and reaction is called diarzon process.

$$C_2H_5OH + SOCI_2 \rightarrow C_2H_5CI + HCI + SO_2$$

Meachanism

Thionyl chloride

$$R \xrightarrow{C} S = O \xrightarrow{C} R^{\pm} \xrightarrow{S} = O \xrightarrow{(fast)} R \xrightarrow{C} S = O :$$

Chlorosulfite ester

Ion pair

This mechanism resembles the $S_N 1$, except that the nucleophile is delivered to the carbocation by the leaving group, giving retension of configuration as shown in this following example. (Under different conditions, retension of configuration may not be observed).

4.10 Action of Phosphorus Halides (PX₅ and PX₃)

Phosphorous halide react with alcohols to form corresponding haloalkanes.

For Example:
$$C_2H_5OH + PCI_5 \rightarrow C_2H_5CI + HCI + POCI_3$$

Mechanism:

$$3 R-OH+PCI_5 \longrightarrow P (OR)_3CI_2+3HCI$$

$$P(OR)_2CI_2+ROH \longrightarrow P (OR)_3CI+HCI$$

$$(OR)_3P \longrightarrow (OR)_3P=O+RCI$$

$$(RO_3)P=O+3HCI \longrightarrow P \longrightarrow P (OR)_3CI+HCI$$

$$(OR)_3P \longrightarrow P \longrightarrow P (OR)_3CI+HCI$$

4.11 Action of Ammonia

When vapours of ammonia with alcohol passed over heated alumina mixture of primary, secondary and tertiary amines is formed.

$$ROH + NH_3 \xrightarrow{Al_2O_3} RNH_2 \xrightarrow{ROH} R_2NH \xrightarrow{ROH} R_3N$$

$$1^0 amine \qquad \qquad 2^0 amine \qquad \qquad 3^0 amine$$

The ease of dehydration of alcohols is in the order Tertiary > Secondary > Primary

4.12 Dehydration

Alcohols undergo dehydration (removal of a molecule of water) to form alkenes on treating with acid e.g., concentrated H_2SO_4 or H_3PO_4 or catalysts such as anhydrous zinc chloride or alumina

Mechanism of dehydration

Step 1:
$$H - C - C - O - H + H^{+} \xrightarrow{Fast} H - C - C - O^{+} - H$$

Ethanol

Ethyloxonium ion)

Step 3:
$$H - C \stackrel{H}{\stackrel{}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}{\stackrel{}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}{\stackrel{}}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}{\stackrel{}}$$

The acid used in step 1 is released in step 3. To drive the equilibrium to the right, ethane is removed as it is formed. The relative ease of dehydration, i.e., $3^{\circ} > 2^{\circ} > 1^{\circ}$, of alcohols follows the order of stability of carbonium ions.

- (a) With heated alumina (Al₂O₃): When vapours of an alcohol are passed over heated alumina, different products are obtained at different temperatures as given below:
 - (i) At 513 523 K (240° 250° C), intermolecular dehydration takes places to form ethers e.g.,

2CH₃CH₂OH
$$Al_2O_3$$
 $CH_3CH_2-O-CH_2CH_3+H_2O$
Ethyl alcohol Diethyl ether

(ii) At 633 K (360°C), intermolecular dehydration takes place to form alkenes, e.g.,

$$\begin{array}{ccc} \text{CH}_3\text{CH}_2\text{OH} & \xrightarrow{& \text{Al}_2\text{O}_3\\ & \text{Ethanol} & & \text{Ethene} \end{array}$$

4.13 Oxidation of Alcohols

(a) Oxidation: Oxidation of alcohols involves the formation of carbon-oxygen double bond with cleavage of O–H and C–H bond.

$$H - \stackrel{I}{C} - O - H \longrightarrow C = O + H_2$$

These are also called dehydrogenation reactions since it involves loss of hydrogen from the alcohol molecule. The oxidation of alcohols can be carried out with a variety of reagents such as neutral, acidic or alkaline $KMnO_4$, acidified $K_2Cr_2O_7$ or dil. HNO₃. The ease of oxidations and nature of the products, however, depends upon the type of alcohol used.

(i) Primary Alcohols are easily oxidized first to aldehydes and then to acids, both containing the same number of carbon atoms as the original alcohol.

E.g.,
$$CH_3CH_2OH + [O] \xrightarrow{K_2Cr_2O_7 + DilH_2SO_4} CH_3CHO \xrightarrow{[O]} CH_3COOH$$

Ethyl alcohol Acetic acid

The oxidation can, however, be stopped at the aldehyde stage if Cr(VI) reagent such as Collin's reagent (CrO₃.2C₅H₅N, chromium trioxide-pyridine complex), Corey's reagent or pyridinimum chlorochromate (PCC, CrO₃.C₅H₅N.HCl or C₅H₅NH + CrO₃Cl⁻) pyridinimum dichromate [PDC, (C₅H₅NH)₂²⁺ Cr₂O₇²⁻] in anhydrous medium (i.e., CH₂Cl₂) are used as the oxidizing agents.

RCH₂OH
$$C_5H_5NH^+CrO_3Cl^-(PCC)$$
 $R-C-H$
1° Alcohol Aldehyde

(ii) Secondary Alcohols are easily oxidized to ketones with the same number of carbon atoms. However, ketones resist further oxidation but in some conditions, they are oxidized to carboxylic acids containing lesser number of carbon atoms than the original alcohol.

CH₃ CHOH
$$K_2Cr_2O_4/H_2SO_4$$
 CH₃ C = O $K_2Cr_2O_4/H_2SO_4$ CH₃COOH + CO₂ + H₂O Acetic acid

Isopropyl alcohol

Acetone

OH O II O II CH₃-CH-CH₂CH₂CH₃
$$\stackrel{[O]}{\longrightarrow}$$
 CH₃-C-CH₂CH₂CH₃ $\stackrel{[O]}{\longrightarrow}$ CH₂COOH - HOOCCH₂CH₃ Pentane-2-one Acetic acid Propionic acid

This oxidation be stopped at the ketone stage by using chromic anhydride (CrO₃)

$$R-CH-R' \xrightarrow{CrO_3/C_5H_5N} R-CH-R'$$

$$OH \qquad O$$
Ketone

(iii) **Tertiary Alcohols** are resistance to oxidation in neutral or alkaline KMnO₄ solution but are readily oxidized in acidic solution (K₂Cr₂O₇/H₂SO₄ or KMnO₄/H₂SO₄) to a mixture of a ketone, and an acid each containing lesser number of carbon atoms than the original alcohol. The oxidation presumably occurs via alkenes formed through dehydration of alcohols under acidic conditions. For example

$$\begin{array}{c} CH_{3} \\ CH_{3} \\ CH_{3} \\ CH_{3} \\ \end{array} \\ C-OH \xrightarrow{H^{+}} CH_{3} \\ C-C=CH_{2} \\ \end{array} \\ \begin{array}{c} CH_{3} \\ C-CH_{3} \\ \end{array} \\ C=O+[HCOOH] \xrightarrow{[O]} CO_{2}+H_{2}O \\ CH_{3} \\ \end{array} \\ C=C+CH_{2} \\ CH_{3} \\ C-CH_{2} \\ CH_{3} \\ C-C+CH_{2} \\ CH_{3} \\ C-C+CH_{3} \\ \end{array} \\ \begin{array}{c} CH_{3} \\ C-C+CH_{3} \\ C-C+CH_{3} \\ C-C+CH_{3} \\ \end{array} \\ \begin{array}{c} CH_{3} \\ C-C+CH_{3} \\ C-C+CH_{3} \\ \end{array} \\ \begin{array}{c} CH_{3} \\ C-C+CH_{3} \\ C-C+CH_{3} \\ \end{array} \\ \begin{array}{c} CH_{3} \\$$

4.14 Oppenauer Oxidation

The aluminium-catalyzed hydride shift from the α -carbon of an alcohol component to the carbonyl carbon of a second component, which proceeds over a six-membered transition state, is named Meerwein-Ponndorf-Verley-Reduction (MPV) or Oppenauer Oxidation (OPP) depending on the isolated product. If aldehydes or ketones are the desired products, the reaction is viewed as the Oppenauer Oxidation.

Non-enolizable ketones with a relatively low reduction potential, such as benzophenone, can serve as the carbonyl component used as the hydride acceptor in this oxidation.

Action of heated copper: Different classes of alcohols give different products when their vapors are passed over heated copper at 573 K (300° C)

(a) Primary alcohols undergo dehydrogenation to give aldehydes.

$$\begin{array}{ccc} \text{CH}_3\text{CH}_2\text{OH} & \xrightarrow{\text{Cu/573K}} & \text{CH}_3 \text{ CHO} & +\text{H}_2 \\ \text{Ethanol} & & \text{Ethanal} \\ \text{Ethyl alcohol} & & \text{Acetaldehyde} \end{array}$$

(b) Secondary alcohols also undergo dehydrogenation to give ketones.

$$CH_3 COH CU/573K CH_3 C = O + H_2$$

$$CH_3 COH CH_3 CH_3 C = O + H_2$$

$$CH_3 COH_3 COH_3 CH_3 CH_3 CH_3$$

$$CH_3 COH_3 COH_3 CH_3 CH_3$$

$$CH_3 COH_3 COH_3 CH_3$$

$$CH_3 COH_3 COH_3$$

$$CH_3 COH_3 COH_3$$

$$CH_3 COH_3 COH_3$$

$$CH_3 COH_3$$

(c) Tertiary alcohols, however, undergo dehydration to form alkenes.

$$CH_{3} - CH_{3} - C$$

4.15 Pinacol-Pinacolone Rearrangement Reaction

When pinacols (mostly ditertiary alcohols) are treated with mineral acids, acid chlorides, $ZnCl_2$ or other electrophilic reagent, they rearrange to form ketones called pinacolones with the elimination of H_2O .

Mechanism:

(tert-Butyl alcohol)

4.16 Dihydric Alcohols

Ethylene glycol or ethane-1, 2-diol

(a) Preparation:

(i)
$$3CH_2 = CH_2 + (alkaline) KMnO_4 + 4H_2O$$

 \longrightarrow $3HOH_2C-CH_2OH+2MnO_2+2KOH$

(ii)
$$CH_2 = CH_2 \xrightarrow{O_2/Ag} O$$
 (Epoxy ethane) or (Ethylene epoxide) $\xrightarrow{H_2O/473K} HOH_2C-CH_2OH$

Ethylene glycol undergoes extensive intermolecular H-bonding. As a result, dihydric alcohols are highly associated and have high b.p., high viscosity, and are highly soluble in H₂O.

(b) Reactions:

(i)
$$HOCH_2-CH_2OH \xrightarrow{PCl_5 \text{ or HCl, 433K}} CH_2CI-CH_2CI$$

(ii)
$$HOCH_2 - CH_2OH \xrightarrow{2H_1 - H_2O} [I-CH_2-CH_2-I]$$

$$\longrightarrow CH_2 = CH_2+I_2$$

(iii)
$$HOCH_2-CH_2OH+HNO_3 \xrightarrow{H_2SO_4} CH_2ONO_2+2H_2O$$

$$CH_2ONO_2$$
Ethylene dinitrate

(iv)
$$HOCH_2-CH_2OH \xrightarrow{CH_3COOH/H_2SO_4} CH_2O COCH_3$$

 CH_2OCOCH_3
Glycol diacetate

(c) Oxidation: Ethylene glycol on oxidation with conc. HNO₃ mainly gives glycolic acid and oxalic acid. The other oxidation products such as glyoxal and glyoxalic acid are also formed in small quantities because they are more readily oxidized than glycol itself.

$$\begin{array}{c} \text{HOCH}_2\text{-}\text{CH}_2\text{OH} \\ \longrightarrow \text{OCH-}\text{CH}_2\text{OH} \xrightarrow{[O]} \text{HOOC-}\text{CH}_2\text{OH} \\ \text{Glycoaldehyde} & \text{Glycollic acid} \\ \downarrow [O] & \downarrow [O] \\ \text{OHC-}\text{CHO} \xrightarrow{[O]} \text{HOOC-}\text{CHO} \xrightarrow{[O]} \text{(COOH)}_2 \\ \text{Glyoxal} & \text{Glyoxalic acid} & \text{Oxalic acid} \end{array}$$

(d) Dehydration:

(i)
$$HOCH_2 - CH_2OH \xrightarrow{773K} O + H_2O$$

(ii)
$$HOCH_2 - CH_2OH \xrightarrow{Anhd.ZnCl_2} [CH_2 = CHOH]$$

Vinyl alcohol
Tautomerise $CH_3 - CHO$

(iii) With conc.
$$H_2SO_4$$
: $HO - CH_2 - CH_2 - O$ H $Conc. H_3SO_4 $distill$ $O - CH_2 - CH_2 - OH$ $O - CH_2 - CH_2 - OH$$

(iv)
$$HO - CH_2 - CH_2OH \xrightarrow{Conc.H_3PO_4} \frac{Conc.H_3PO_4}{distill}$$

 $H - O - CH_2 - CH_2 - OH$
 $CH_2 - CH_2OH$
 O
 $CH_2 - CH_2OH$
Diethylene glycol

Trihydric Alcohols; Glyerol or Glycerine 1, 2, 3-Propanetriaol

(a) Preparation:

(i)
$$CH_3CH = CH_2 \xrightarrow{Cl_2773K} CI - CH_2 - CH = CH_2$$

$$\xrightarrow{\text{aq. KOH or aq. Na}_2CO_3} HO - CH_2 - CH = CH_2$$

$$\xrightarrow{\text{Allyl alcohol}} HO - CH_2 - CHCI - CH_2OH$$

$$\xrightarrow{\text{aq. NaOH}} HO - CH_2 - CHOH - CH_2OH$$

- **(b) Properties:** Due in the presence of three (–OH) groups, it undergoes extensive intermolecular H-bonding and thus it has high boiling point viscosity and is highly soluble in H₂O.
- (c) Reaction: When glycerol is treated with a small amount of HI or Pl₃ allyl iodide is formed.

$$\begin{array}{c} \text{HOCH}_2\text{--CHOH--CH}_2\text{OH} \xrightarrow{3\text{HI}(-3\text{H}_2\text{O})} & \text{[ICH}_2\text{--CHI--CH}_2\text{I]} \xrightarrow{I_2} \text{CH}_2 = \text{CH--CH}_2\text{I} \\ \text{1,2,3-Triiodopropane (glycerol tri-iodide)} & \text{Allyliodide} \\ \text{(Unstable)} \end{array}$$

When large moment of HI is used, the main product is isopropyl iodide.

$$CH_{2} = CH - CH_{2}I \xrightarrow{+HI} [ICH_{3} - CHI - CH_{2}I]$$
Allyliodide
$$\downarrow -I_{2}$$

$$CH_{3} - CHI - CH_{3} \xleftarrow{+HI} CH_{3} - CH = CH_{2}$$

(d) Nitration:

HOCH₂-CHOH-CH₂OH
$$\xrightarrow{\text{Conc.HNO}_3}$$
 +Conc. H₂SO₄ $\xrightarrow{\text{Conc.HNO}_2}$ O₂NOCH₂-CHONO₂-CH₂ONO₂ (Glyceryl trinitrate) (Nitroglycerine)

A mixture of glycerol trinitrate and glyceryl dinitrate absorbed on Kieselguhr is called dynamite discovered by Alfred Noble.

(e) Dehydration with KHSO₄ or conc. H₂SO₄:

$$HOCH_2 - CHOH - CH_2OH \frac{KHSO_4 \cdot 473-508K}{-2H_2O}$$
 $CH_2 = CH - CHO \frac{Unstable}{Tautomerisation} [CH_2 = C = CHOH]$

(f) Oxidation:

- (i) With dil. HNO₃, a mixture of glyceric and tartaric acid is obtained.
- (ii) With conc. HNO₃ mainly glyceric acid is obtained.
- (iii) With bismuth nitrate, only mesoxalic acid is obtained.
- (iv) Mild oxidizing agent, such as Br_2 water, sodium hypobromite ($Br_2/NaOH$) and fenton's regagent ($H_2O_2 + FeSO_4$) give a mixture of glyceraldehyde and dihydroxy acetone. This mixture is called glycerose.
- (h) With acidic KMnO₄: $HOCH_2-CHOH-CH_2OH + 6[O]$ $\longrightarrow HOOC-COOH$ (oxalic acid) $+ CO_2 + 3H_2O$
 - (i) Reaction with oxalic acid: When oxalic acid is heated with glycerol at 383 K, it forms glycerol mono-oxalate which loses a molecule of CO₂ to give glycerol mono- formate which in turn on hydrolysis gives formic acid.

HOCH₂-CHOH-CH₂OH + HO OCH-COOH
$$\frac{\Delta}{-CO_2}$$
 CH₂ = OOC-COOH $\frac{383 \text{ K}}{-H_2O}$ COOH

COOH

CH₂OH

HOH₂C-CHOH-CH₂† OOCH HOH

OH H

HCOOH + HOH₂C-CHOH - CH₂OH

(ii) At 230° C (503 K), oxalic acid reacts with glycerol to form glycerol dioxalate which loses two molecules of CO₂ to give allyl alcohol.

5. DISTINCTION BETWEEN PRIMARY, SECONDARY AND TERTIARY ALCOHOLS

(a) Lucas test: This test is based on the difference in the three types of alcohols (having δ or less carbon towards Lucas reagent (a mixture of conc. Hydrochloric acid and anhydrous zinc chloride)

$$ROH + HCI \xrightarrow{ZnCl_2} RCI + H_2O$$

Since alkyl halides are insoluble, their formation is indicated by the appearance of a turbidity in the reaction mixture. The order of reactivity is tertiary >secondary >primary, the tertiary alcohols produce turbidity immediately, the secondary alcohols give turbidity within 5 – 10 minutes, and the primary alcohols do not give turbidity at all, at room temperature.

- (b) Catalytic dehydrogenation (action of reduced copper at 300°). Discussed earlier,
 - (i) Primary alcohols form aldehydes
 - (ii) Secondary alcohols form ketones.
 - (iii) Tertiary alcohols form olefins.
- **(c) Victor Meyer test:** This test is based on the different behaviour of primary, secondary and tertiary nitroalkanes towards nitrous acid. The test involves the following steps.
 - (i) Alcohols is treated with concentrated hydroiodic acid or red phosphorus and iodine to form the corresponding alkyliodide.
 - (ii) Alkyl iodide is reacted with silver nitrite to form the corresponding nitroalkane.
 - (iii) The nitroalkane is treated with nitrous acid (NaNO₂ + HCl) followed by treatment with alkali (NaOH or KOH). Upon such treatment different alcohols give different colours.
 - Primary alcohols produce a blood red colour
 - Secondary alcohols produce a blue colour
 - Tertiary alcohols produce no colour.

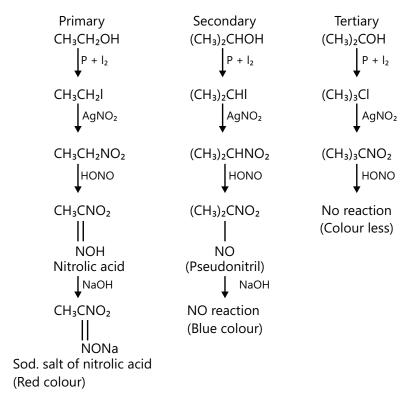

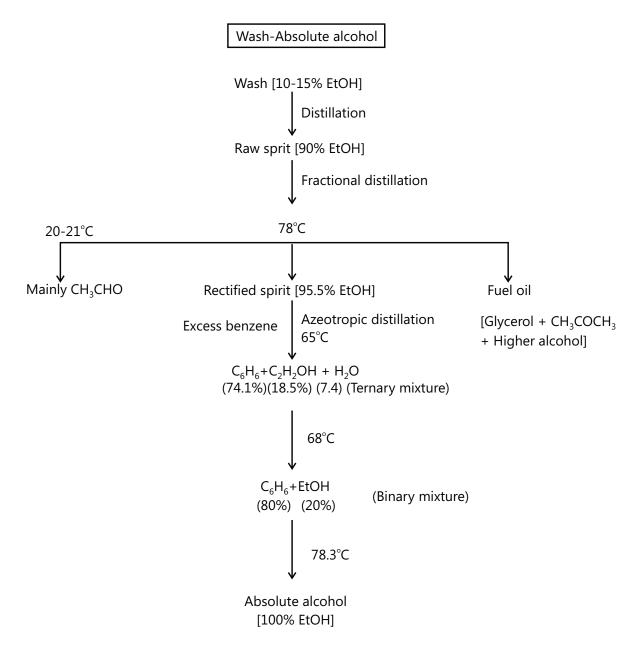

Illustration 5: Give the structure of the major organic product when 3-ethylpent-2-ene is treated with $Hg(OAc)_2$, H_2O , $NaBH_4$. (**JEE MAIN**)

Sol:

$$\begin{array}{c} \text{CH}_2\text{CH}_3 \\ \text{I} \\ \text{CH}_3\text{CH}_2 - \text{C} = \text{CH} - \text{CH}_3 \\ \text{3-Ethylpent-2-ene} \end{array} \xrightarrow{\text{Hg(OAc)}_2/\text{H}_2\text{O}} \begin{array}{c} \text{CH}_2\text{CH}_3 \\ \text{I} \\ \text{CH}_3\text{CH}_2 - \text{C} - \text{CH} - \text{CH}_3 \\ \text{I} \\ \text{OH HgOAc} \end{array} \xrightarrow{\text{Reduction}} \begin{array}{c} \text{CH}_2\text{CH}_3 \\ \text{I} \\ \text{Reduction} \end{array} \xrightarrow{\text{CH}_2\text{CH}_3} \\ \text{CH}_3\text{CH}_2 - \text{C} - \text{CH}_2\text{CH}_3 \\ \text{I} \\ \text{OH} \\ \text{3-Ethylpentan-3-ol} \end{array}$$

Absolute alcohol:

Flowchart 22.1 Preparation of absolute alcohol

Chemical properties of alcohols:

- (a) Rate of reaction of alcohols with carbonyl compounds depends on two factors:
 - (i) Leaving group ability of the substituent: Better the leaving group, faster the reaction.
 - (ii) Bulkiness of the alkyl part of alcohol: Bulkier the alkyl part, slower is the reaction because of steric hinderance.
- (b) Only alkyl methyl ether can be prepared by reaction of alcohol with Diazomethane.
- (c) In reaction of alcohols with excess of sulphuric acid at lower temperatures, we obtain ethers. But, as the temperature increases, alkenes become the favourable product. Also, in case of secondary and tertiary alcohols, alkene is the predominant product due to ease of elimination.
- **(d)** In reaction of alcohols with $SOCl_2$ it proceeds via S_N i mechanism. Thus, the configuration in case of chiral carbon is retained. But, if pyridine is used as a solvent, the reaction proceeds via S_N 2 mechanism with inversion of configuration.
- (e) In reaction of alcohols with PCl_s and PCl₃ proceeds via S_N2 mechanism.
- **(f)** Weak oxidizing agents like PCC, PDC etc oxidize 1^o alcohols to aldehydes while strong reagent oxidizes 1^o alcohols to carboxylic acids. All these oxidizing agents oxidize 2^o alcohols to ketones but 3^o alcohols are not affected.
- **(g)** In pinacol-pinacolone rearrangement, With unsymmetrical glycols, the product obtained is determined mainly by the OH that is lost as H₂O to give more stable carbocation and, thereafter, by the better migrating group.
 - (i) The order of migratory aptitudes is Ar > > H > R.
 - (ii) The migratory order in aryl: Ar containing more e⁻-donating (or more e⁻ rich) migrates. For example,

$$MeO \longrightarrow Me \longrightarrow Ph->CI \longrightarrow p-Chlorophenyl$$

- (iii) The phenyl group is more e⁻ rich than (Me) group, therefore, (Ph) group migrates in preference of (Me) group
- (iv) The migrating group should be trans (anti) to the leaving (–H) group.
- (v) The (–OH) group will be lost from the C atom which would leave the most stable carbocation.
- (vi) The rate determining step (R.D.S. and slow) is the formation of stable carbocation, i.e., conversion in step 2 to step 3.

T P Varun (JEE 2012, AIR 64)

Illustration 6: Arrange the following compounds in the decreasing order of their b.p s' and solubility in H₂O.

(JEE MAIN)

(a) (I) Methanol (II) Ethanol (III) Propan-1-ol

(IV) Butan-1-ol (V) Butan-2-ol (VI) Pentan-1-ol

(b) (l) Pentanol (II) n-Butane (III) Pentanal

(IV) Ethoxy ethane

- Pentane (c) (1)
- (II) Pentane 1, 2, 3-triol
- (III) Butanol
- **Sol:** (c) **B.P.** order: VI > IV > V > III > II > I

Solubility order: | > | | > | | > | V > | V > V |

Explanation: All of the mare alcohol so all have H-bonding. As the molecular mass and surface area increases, the B.P. increases and solubility decreases.

Out of (IV) and (V), there is branching in (V) and has less surface are than (IV), So the boiling point of (IV) > (V), but solubility of (V) > (IV)

- (b) **B.P.order**:
- | > ||| > |V > ||
- Solubility order: | > ||| > |V > ||

In (I), there is H-bonding, in (II) (aldehyde), dipole-dipole interaction, in (III) (ether), slightly polar due to EN of O and in (IV) (alkane), Van der Waals interaction (non-polar)

- (c) **B.P. Order:** || > ||| > |
 - **Solubility Order:** || > ||| > |

In (II), there (–OH) groups, more H-Bonding; in (II), one (–OH) group, less H-bonding; in (I) (alkane), Van der Waals interaction

Illustration 7: Explain the following:

(JEE MAIN)

- (a) Which has higher B.P.?
 - (i) Phenol (ii) Benzenethiol
- (b) Which has higher melting point?
 - (i) Hydroquinone (ii) Catechol
- (c) Explain the less solubility and lower b.p. of:
 - (i) o-Nitrophenol (ii) o-Hydroxy benzaldehyde
 - (iii) o-hydroxybenzoic acid (salicylic acid) compared with their p-and m-isomers.

Sol: (a) Although the molecular mass of benzenethiol (Ph - SH) is higher, phenol has high boiling point. It is because there is no H-bonding in PhSH.

(b) Hydroquinone
$$\left(HO - OH\right)$$
 (I) has high M.P. than catechol

(II) because of the

Symmetrical packing of p- is its crystal lattice which requires more energy for its melting.

(c) In ortho-isomers of (I), (II) and (III), intramolecular H-bonding (chelation) occurs which inhibits the intermolecular attraction between these molecules and thus, lowers the b.p. and also reduces

o-Nitophenol

o-Hydroxybenzaldehyde (Salicylaldehyde)

o-Hydroxybenzoic acid (Salicylic acid)

H-bonding of these molecules with H₂O thereby, decreases water solubility. Intermolecular chelation does not occur in p –and m-isomers.

Illustration 8: Synthesize the following:

(JEE MAIN)

PHENOLS

1. INTRODUCTION

When OH group is attached at benzene ring, the compound is known as phenol

Nomenclature of Phenols

Some dihydric and trihydric phenols are given below:

2. METHODS OF PREPRATION OF PHENOLS

2.1 From Haloarenes

2.2 From Benzenesulphonic Acid

$$\begin{array}{c}
SO_3H & OH \\
\hline
(i) NaOH \\
\hline
(ii) H^+
\end{array}$$

2.3 From Diazonium Salts

$$\begin{array}{c|c} NH_2 & \stackrel{+}{N_2}C^{-1} \\ \hline & NH_2 \\ \hline & (I) \ NaNO_2 \\ \hline & (ii) \ +HCI \\ \hline & Benzene \ diazonium \\ \hline & chloride \\ \end{array} + N_2 + HCI$$

When diazonium salts react with water vapour it gives phenol.

2.4 From Cumene

When cumene (isopropylbenzene) is oxidized in the presence of air and acid, it gives phenol and acetone.

3. PHYSICAL PROPERTIES OF PHENOLS

- (a) Pure phenols are generally colorless solids or liquids. The light colour usually associated with phenols is due to its oxidations by air in presence of light.
- **(b)** Phenols, generally are insoluble in water; but phenol itself, and polyhydric phenols are fairly soluble in water which is believed to be due to the formation of hydrogen bond with water.
- (c) Due to intermolecular hydrogen bonding, phenols usually have relatively high boiling points than the corresponding hydrocarbons aryl halides and alcohols. For example, phenol (mol. Wt. 94) boils at 182°C while toluene (mol. Wt. 92) boils at 110°C.

Higher b.p. than alcohols is due to higher polarity of the O-H bond and consequently stronger intermolecular hydrogen bonding in phenols than in alcohols. Appreciable solubilities of the phenol and polyhydric phenols in water is also due to strong hydrogen bonding between phenols and water molecules.

Intermolecular hydrogen bonding phenols

$$Ar$$
 $O-H$ O H

Hydrogen bonding between phenols and water molecules

o-Nitro phenol (Intermolecular H-bonding possible due to close mass of NO₂ and -OH groups)

Phenols containing groups like-NO₂ or –COOH in the ortho position to the –OH group can also form intermolecular hydrogen bonds (e.g. o-nitro phenol) which is responsible for their lower boiling points and less solubility in water than the corresponding meta or para isomer. Due to possibility of intermolecular hydrogen bonding (also known as chelatom) in the ortho isomer, intermolecular hydrogen bonding is not possible and hence the ortho isomer can neither get associated nor can from hydrogen bonding with water with the results it has a low b p. and less solubility in water than the meta and para isomers which can associate (union of two or more molecules of the same speoins) as well as can form hydrogen bonding with water.

p-Nitro phenol (1 molecules) (intermolecular H-bonding) is not possible due large distance between-NO₂ and -OH occups hence intermolecular H-bonding is possible.

$$0H \longrightarrow 0 \stackrel{\mathsf{H}}{\longleftarrow} H$$

Hydrogen bonding between p-nitro and water

- **(d)** They possess characteristic colour. They are highly toxic in nature and possess antiseptic properties. They may produce wounds on skin.
 - (i) Phenol exists as resonance hybrid of the following structures.

$$\stackrel{\circ}{\text{I}} H \stackrel{\circ}{\text{I}} H \stackrel{\circ$$

Due to resonance oxygen atom of the –OH group acquires & positive charge (see structures III to V) and hence attract electron pair of the O–H bond leading to the release of hydrogen atom as proton.

Since resonance is not possible in alcohols (due to absence of conjugation of the lone pair of electron of oxygen with a double bound), the hydrogen atom is more firmly linked to the oxygen atom and hence alcohols are neutral in nature.

(ii) Once the phenoxide ion is formed, is stabilizes itself by resonance, actually phenol acid ion is more stable than the parent phenol.

$$\bigvee_{V} \bigvee_{VI} \bigvee_{VII} \bigvee_{VIII} \bigvee_{VIIII} \bigvee_{VIII} \bigvee_{VIII} \bigvee_{VIII} \bigvee_{VIII} \bigvee_{VIII} \bigvee_{VIII} \bigvee_{VIIII} \bigvee_{VIIIII} \bigvee_{VIIII} \bigvee_{VIIIII} \bigvee_{VIIII} \bigvee_{VIIIII} \bigvee_{VIIII} \bigvee_{VIIIII} \bigvee_{VIIII} \bigvee_{VIIIII} \bigvee_{VIIII} \bigvee_{$$

Comparison of acidity of phenols and carbonic acid

Relative acidity of the various common compounds.

 $RCOOH > H_2CO_3 > C_6H_5OH > HOH > ROH$ Carboxylic acid Carbonic acid Phenol Water Alcohols.

4. CHEMICAL PROPERTIES OF PHENOLS

4.1 Nitration

(a) When phenol react with dilute nitric acid at low temperature (290 K), give a mixture of ortho and para nitro phenols.

(b) When phenols react with concentrated nitric acid, it gives 2, 4, 6-trinitrophenol.

$$OH O_2 N O_2$$

$$Conc.HNO_3 NO_2$$

2,4,6-Trinitrophenol (Picric acid)

4.2 Halogenation

(a) When the reactions carried out in solvents of low polarity such as CHCl₃ or CS₂ and at low temperature, monobromophenols are formed.

$$\begin{array}{c|c}
OH & OH \\
\hline
Br_2 in CS_2 \\
\hline
273 K & Minor & Br \\
\hline
Major
\end{array}$$

(b) When phenol is treated with bromine water 2, 4, 6-tribromophenol is formed as white precipitate.

$$OH$$
 $+ 3Br_2$ Br Br

2,4,6-Trinitrophenol

4.3 Kolbe's Reaction

$$\begin{array}{c}
\text{OH} & \text{ONa} \\
\text{NaOH} & \text{Oi) CO}_2 \\
\hline
\text{(ii) H}^*
\end{array}$$

2-Hydroxybenzoic acid (Salicylic acid)

Mechanism of Reaction

4.4 Reimer-Tiemann Reaction

On treating phenol with chloroform in the presence of sodium hydroxide, a–CHO group is introduced at ortho position of benzene ring. This reaction is known as Reimer – Tiemann reaction. The intermediate substituted benzal chloride is hydrolyzed in the presence of alkali to produce salicyladehyde.

The mechanism of the Reimer – Tiemann reaction is believed to involve the formation of dichloromethylene.

$$\mathsf{NaOH} + \mathsf{CHCl}_{\scriptscriptstyle 3} \to \mathbf{:} \mathsf{CCl}_{\scriptscriptstyle 2} + \mathsf{NaCl} + \mathsf{H}_{\scriptscriptstyle 2}\mathsf{O}$$

$$CCI_{2} \longrightarrow CI_{2} \longrightarrow$$

Phenols with blocked p-positions give cyclohexadienones containing the dichloromethyl group.

In the Reimer-Tiemann reaction, the o-isomer predominates, but if one of the o-position is occupied the aldehyde group tend to go to the p-positions; e.g. guaiacol forms vanillin

4.5 Libermann's Reaction

When phenol is treated with sodium dissolved in conc. Sulphuric acid a red colouration appears which changes to blue on adding aqueous NaOH. This reaction is called Libermann's reaction.

$$2NaNO_2 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HNO_2$$
Nitrous acid
$$HO \longrightarrow H + H - O - N = O \longrightarrow HO \longrightarrow N = O \longrightarrow O = \longrightarrow = N - OH$$

$$p-nitrosophenol$$

$$H- \bigcirc O-OH \longrightarrow P$$

$$p-nitrosophenol$$

$$H- \bigcirc O-OH \longrightarrow P$$

$$p-nitrosophenol$$

$$NaOH \longrightarrow P$$

$$Na$$

4.6 Reaction of Phenol with Zinc Dust

When phenol is heated with zinc dust, it gives benzene.

4.7 Oxidation

Oxidation of phenol with chromic acid produces a conjugate diketone known as benzoquinone. In the presence of an oxidizing agent, phenols are slowly oxidized to dark coloured moisture containing benzoquinone.

$$\begin{array}{c}
OH \\
Na_2Cr_2O_7 \\
H_2SO_4
\end{array}$$
Benzoquinone

5. DISTINCTION BETWEEN ALCOHOL AND PHENOLS

- (a) Phenols turns blue litmus red but alcohols do not.
- (b) Phenols neutralize base, while alcohols do not.

OH ONa
$$+ \text{NaOH} \longrightarrow + \text{H}_2\text{O}$$

R-OH + NaOH — No reaction

(c) Phenols give violet colour with FeCl₃. while alcohols do not.

3
$$\longrightarrow$$
 + FeCl₃ \longrightarrow \bigcirc \bigcirc Fe + 3HC
Violet
R-OH + FeCl₃ \longrightarrow No reaction

Illustration 1: Identify the major products in the following reactions:

(I)
$$HNO_3$$
 H_2SO_4
 CH_3
 CH_3
 $Water$
 HO_3
 H_2SO_4
 CH_3
 H_2SO_4
 R_3
 R_4
 R_5
 R_5

Sol: (I) The nitrating mixture gives the attachment of the nitro group on the ortho position. The presence of methoxy group is an electron-donating groupwhich makes the ortho position more electron-rich enabling the attachment of the electron-withdrawing NO_2 group.

(II) Bromine is an electrophile and the presence of electron donating groups i.e. -OH and CH_3 make the ortho and the para positions available for the attachment.

$$A = O_2N \longrightarrow Br OH$$

$$NO_2$$

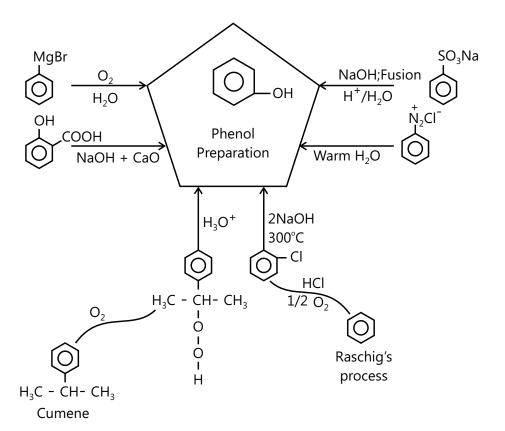

$$B = CH_3$$

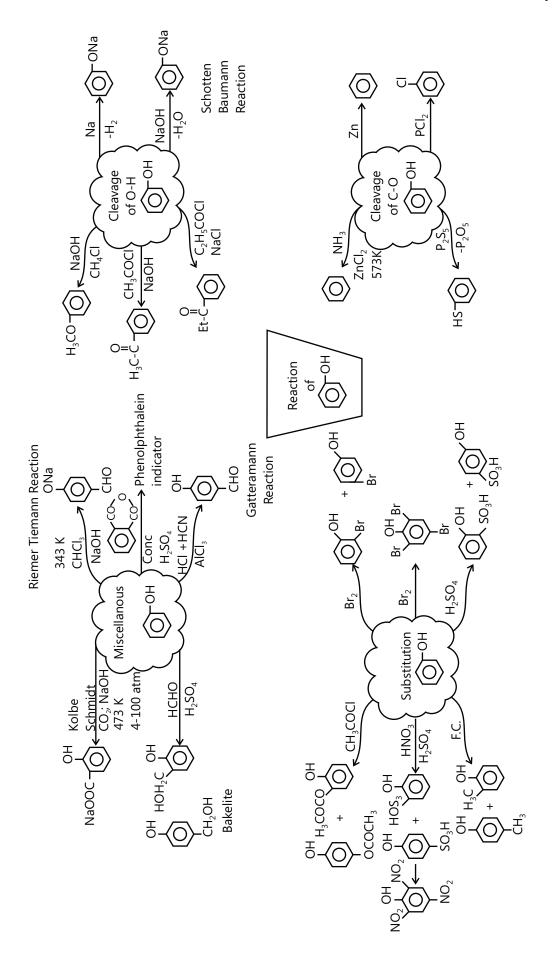

MASTERJEE CONCEPTS

- Phenols although colourless turn reddish due to atmospheric oxidation.
- Phenols and alcohol have high boiling point due to intermoelcular hydrogen bonding
- Out of three isomeric nitrophenols, only ortho isomer is steam volatile and has lesser solubility and lower boiling point than meta and para. Ortho cannot form H-bond with water and in ortho there exist intramolecualr H- Bonding.
- Phenols are stronger acids than alcohols but weaker than carboxylic acid and carbonic acid.
- Phenols are stronger acids than alcohols because the phenoxide ion formed after the release of proton is stabilised by resonance where as alkoxide ion does not.
- TEST OF PHENOL– Phenols give violet colour with neutral FeCl₃. Depending upon the nature of Phenol, colour varies from violet to blue green or even red.
- Preparation of phenol from cumene proceeds via peroxide radical mechanism.

Saurabh Chaterjee JEE Advanced 2013, AIR

POINTS TO REMEMBER

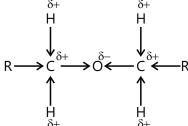

ETHERS

1. INTRODUCTION

The ethers are those compounds that have a C-O-C in their structure where, importantly, each C can only be part of an alkyl or an aryl group – i.e. R–O–R'. The electronegative oxygen, flanked as it is by two electron pushing alkyl groups, has very little tendency to participate in any reaction. This lack of reactivity is also attributed to the two alkyl groups enveloping the oxygen, shielding it from reagents. The ether molecule appears to have an outer unreactive alkyl shield or sphere with the "reactive" oxygen sitting in the centre.

Without any hydrogens directly attached to the oxygen, the molecules are not capable of forming H-bonds. The consequence of this is that the melting and boiling points are lower than the corresponding alcohols. Compatibility / solubility with water is also affected; though the smallest ether is miscible with $R \longrightarrow C \longrightarrow C \longleftarrow C \longleftarrow R$ water, any increase in the size of the alkyl chain drastically lowers the ether's solubility in water and soon forms immiscible mixtures.

2. METHODS OF PREPARATION OF ETHERS

(a) Williamson' Synthesis: Heating of alkyl halide with sodium or potassium alkoxide gives ether. This is a good method for preparation of simple as well as mixed either.

$$R-X+Na-O-R' \longrightarrow R-O-R'+NaX$$

This method is not applicable to tert alkyl halides because the alkoxide ions being both powerful nucleophiles and bases could bring dehydrogenation of the tertiary alkyl halides to form alkenes.

$$R - ONa \longrightarrow R - O^{-} + Na^{+}$$

$$R - \ddot{O} - Na + R' - X \longrightarrow R - \ddot{O} - R + Nax$$

$$R^{-}O - Na \longrightarrow R - O - R$$

$$R - X + Ar - O - Na \longrightarrow R - O - Ar$$

$$Ar - O - Na \longrightarrow R - O - Ar$$

$$Aryl Ether$$

$$O - CH_{2} - CH_{3}$$

The reactivity of primary (1°) alkyl halide is in the order $CH_3 - CH_3 - CH_2 - CH_3 - CH_2 - CH_2$ and the tendency of the alkyl halide to undergo elimination is 3° > 2° > 1°. Hence for better yield the alkyl halide should be primary of the alkoxide should be secondary or tertiary.

$$C_2H_5Br + NaO - C - \longrightarrow C_2H_5 - O - C + NaBr$$

(b) By Heating excess of alcohols with conc. H₂SO₄ e.g.,

$$C_2H_5 - OH + HO - C_2H_5$$
 $\xrightarrow{conc. H_2SO_4}$ $C_2H_5 - O - C_2H_5 + H_2O$
Ethanol (2 molecules) $C_2H_5 - O - C_2H_5 + C_2O$

Recall that 2° and 3° alcohols under the above conditions give alkenes as the main product. Moreover, this method is limited only for the preparation of simple ethers.

(c) By heating alkyl halide with dry silver oxide (only for simple ethers)

$$C_2H_5I + Ag_2O + IC_2H_5 \longrightarrow C_2H_5OC_2H_5 + 2AgI$$

Remember that reaction of alkyl halides with moist silver oxides ($Ag_2O + H_2O = AgOH$) gives alcohols.

(d) By the use of diazomethane to form methyl ethers.

$$n-C_7H_{15}OH + CH_2N_2 \xrightarrow{BF_3} n-C_7H_{15}OCH_3 + N_2$$
Methyl n-heptyl ether
$$n-C_7H_{15}OH + CH_2N_2 \xrightarrow{BF_3} C_6H_5OCH_3$$
Apicolo

3. PHYSICAL PROPERTIES OF ETHERS

- (d) Due to absence of intermolecular H-bonding, B.P of ether is much lower than isomeric alcohols.
- **(e)** Ethers are slightly polar with some net dipole. (e.g. 1.18 D for diethyl ether.) This is due to a bend structure with bond angle of 110° which causes because of repulsion between bulky alkyl groups.

4. CHEMICAL PROPERTIES OF ETHERS

Ethers are less reactive than compounds containing other functional group. They do not react with active metals like Na, strong base like NaOH, reducing or oxidizing agents.

4.1. Formation of Peroxides

On standing in contact with air, ethers are overrated into unstable peroxides ($R_2O \rightarrow O$) which are highly explosive even in low concentrations. Hence ether is always purified before distillation. Purification (removal of peroxide) can be done by washing ether with a solution of ferrous salt (which reduces peroxide to alcohols) or by distillation with conc. H_2SO_4 (which oxidizes peroxides).

The presence of peroxides in ether is indicated by formation of red colour when ether is shaken with an aqueous solution of ferrous ammonium sulphate and potassium thiocyanate. The peroxide oxidizes Fe²⁺ to Fe³ which reacts with thiocyanate ion to given red colour of ferric thiocyanate

Peroxide + Fe²⁺
$$\longrightarrow$$
 Fe³⁺ $\xrightarrow{CNS^-}$ Fe (CNS)₃
Red

However, the formation of peroxide is prevented by adding a little Cu₂O to it.

4.2 Basic Nature

Owing to the presence of unshared electron pairs on oxygen, ethers are basic, Hence they dissolve in strong acids (e.g., HCl, conc. H₂SO₄) at low temperature to form oxonium salts.

On account of this property ether is removed from ethyl bromide by shaking with conc. H_2SO_4 . The oxonium salts are stable only at low temperature and in a strongly acidic medium. On dilution, they decompose to give back the original ether and acid.

Ether also form coordination complexes with Lewis acids like BF₃, AICl₃ RMgX, etc.

$$R_2\ddot{O}: + BF_3 \longrightarrow R_2O \longrightarrow BF_3$$
 (b) $R_2O + RMgX \longrightarrow R_2O \longrightarrow R_2O \longrightarrow X$

It is for this reason that ethers are used as solvent for Grignard reactions.

4.3 Action of Dilute H₂SO₄ (Hydrolysis)

$$C_2H_5$$
-O- C_2H_5 $\xrightarrow{\text{dil. H}_2SO_4 \text{ heat}}$ $2C_2H_5$ -OH

4.4 Action of Concentration H₂SO₄

$$C_2H_5$$
-O- C_2H_5 + H_2SO_4 (conc.) \longrightarrow $C_2H_5OH + C_2H_5HSO_4$

4.5 Action of Conc. HI or HBr.

(i)
$$C_2H_5$$
-O- C_2H_5 +HI(cold) \longrightarrow C_2H_5 -OH + C_2H_5 +I
(ii) C_6H_5 -O- C_2H_5 +HI \longrightarrow C_6H_5 OH + C_2H_5 I

Mechanism of reaction: S_N^2 and S_N^2 mechanisms for the cleavage of ethers. S_N^2 cleavage occurs at a faster rate with HI than with HCl.

Step 1:
$$R-O-R' + HI \longrightarrow R'$$

$$base_1 \quad acid_2 \quad acid_1 \quad base_2$$
Step 2 for $S_N = I + R \cap R'$

$$Step 3 for $S_N = R \cap R' + I \cap R' = R \cap R'$

$$Step 3 for $S_N = R \cap R' + I \cap R' = R \cap R'$

$$Step 3 for $S_N = R \cap R' + I \cap R' = R \cap R'$

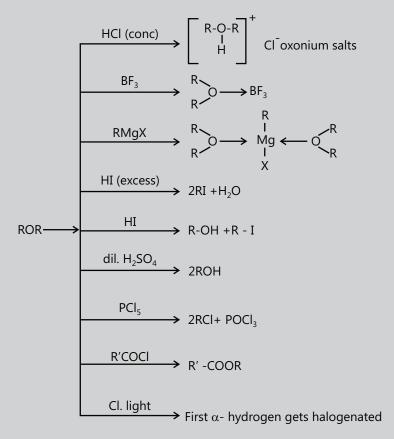

$$Step 3 for $S_N = R \cap R \cap R' = R \cap R' = R \cap R'$

$$Step 3 for $S_N = R \cap R' = R \cap R' = R \cap R' = R \cap R'$$$$$$$$$$$

(a) The transfer of H⁺ to ROR' in step 1 is greater with HI, which is a stronger acid, than with HCl Furthermore, in step 2, I, being a better nucleophile than Cl⁺, reacts at a faster rate.

MASTERJEE CONCEPTS

• Boiling point of ethers is lower than alcohol due to absence of hydrogen bonding.

- In reaction with HI, if cold and dilute HI solution is treated with ether, alcohols are formed while in hot and concentrated HI, alkyl halides are formed.
- The reaction mechanism in case of HI depends on the substrate. If the substrates attached to oxygen are 1° or 2° , then the mechanism is $S_{N}2$ but if the substrate is 3° or the carbocation is very stable then the mechanism is $S_{N}1$.

Nikhil Khandelwal (JEE 2009, AIR 94)

Illustration 1: How are the ethers distinguished from alcohols?

(JEE MAIN)

Sol: (i) All alcohols give CH₄ (methane gas) when reacted with MeMgBr.

$$CH_{3}OH + MeMgBr \longrightarrow CH_{4} \uparrow + CH_{3}OMgBr$$

$$1^{\circ} \text{ alcohol}$$

$$Me \longrightarrow OH + MeMgBr \longrightarrow CH_{4} \uparrow + Me \longrightarrow OMgBr$$

$$2^{\circ} \text{ alcohol}$$

Solved Examples

JEE Main/Boards

Example 1: Complete the following reactions:

a.
$$2Me_3C-Br \xrightarrow{Ag_2CO_3}$$
 (A)

b.
$$2MeOH + MeCH = O + HCI (g) \rightarrow (B)$$

c.
$$MeOH + H_2C = O + HCI(g) \rightarrow (C)$$

Sol:
$$A = Me_3 C - O - Me_3$$
 (Di-t-butyl ether)

Ag⁺ reacts with Br⁻ leaving Me₃C[®] ,which reacts with CO_3^{2-} to give $Me_3C - OCO_2^{\Theta}$. The latter loses CO_2 leaving Me₃COO which reacts with Me₃C[⊕] to give the product. Due to steric hindrance, the yield is less.

Mechanism:

a.
$$Me_3C - Br \xrightarrow{Ag^{\bigoplus}} AgBr + Me_3C \xrightarrow{CO_3^{2^-}} O$$

$$Me_3C - O - CMe_3$$

$$AgBr + Me_3C \xrightarrow{Ag^{\bigoplus}} AgBr + Me_3C \xrightarrow{CO_3^{2^-}} O$$

$$Me_3C - O - CMe_3$$

$$AgBr + Me_3C \xrightarrow{AlCl_3} B \xrightarrow{HNO_3} B \xrightarrow{HNO_3} B$$

$$AgBr + Me_3C \xrightarrow{HNO_3} CO_3 \xrightarrow{H_2SO_4} CO_4 \xrightarrow{H_2SO_4} CO_5 \xrightarrow{H_2SO_4}$$

b. Me
$$-\ddot{O}H \xrightarrow{H^{\bigoplus}} Me^{\bigoplus} + Me - CH = O$$

Me $-CH - OMe \xrightarrow{CI} Me - CH - OMe$

CI

(α Chloroether)

C.
$$CH_2 = 0$$
 \xrightarrow{MeOH} CH_2 \longrightarrow \longrightarrow CH_2 \longrightarrow $CH_$

Example 2: Complete the following reactions:

a Chloroethyl methyl ether

a.
$$C_6H_6 + MeCOCI \xrightarrow{AICI_3} B \xrightarrow{HNO_3} C \xrightarrow{NaBH_4} D \xrightarrow{H_2SO_4} E$$
Benzene (A)

b. (B)
$$\xrightarrow{\text{NaBH}_4}$$
 $F \xrightarrow{\text{H}_2\text{SO}_4}$ $G \xrightarrow{\text{HNO}_3}$ $F \xrightarrow{\text{H}_2\text{SO}_4}$
